

Precision Theory and Jet Mass Distributions

Yang-Ting Chien

Los Alamos National Laboratory, Theoretical Division, T-2

April 13, 2016

11th International Workshop on High-pT Physics in the RHIC & LHC Era
Brookhaven National Laboratory

Outline

- Jet mass
 - Resummation of large logarithms
- Soft-collinear effective theory (SCET)
 - Factorization theorem
 - Renormalization group evolution
 - Medium modification by Glauber interactions
- Conclusions and outlook

Jet mass

$$\begin{aligned}
 m^2 &= \left(\sum_{i \in J} p_i \right)^2 \\
 &= \left(p_c + p_s \right)^2 \\
 &\approx p_c^2 + 2p_c \cdot p_s \\
 &\approx p_c^2 + 2E_J n_J \cdot p_s
 \end{aligned}$$

- Jet mass is a soft radiation sensitive jet substructure observable
- The infrared structure of QCD induces Sudakov logarithms
- Fixed order calculation breaks down at small jet mass m
- Large logarithms of the form

$$\frac{1}{m} \alpha_s^i \left(\log^j \frac{m}{E_J} \text{ or } \log^j R \right), \quad j \leq 2i - 1$$

need to be resummed

- Hadronization affects the position of the peak at small m
- Resummation of $\log R$ is crucial especially for jets with small radii

Resummation precision

$$\frac{1}{m} \alpha_s^i \left(\log^j \frac{m}{E_J} \text{ or } \log^j R \right), \quad j \leq 2i - 1$$

- *All-order* resummation: $i = 1, \dots, \infty$
- Infrared structure of QCD allows the all-order resummation of logarithmically enhanced terms without calculating diagrams at all orders
 - leading-logarithmic (LL) accuracy: $j = 2i - 1$
 - next-to-leading-logarithmic (NLL) accuracy: $j = 2i - 1, 2i - 2$
 - ...
- Nonglobal logs and clustering logs appear at NNLL
 - Resummation is still an open question

Resummation and effective field theory

THE BASIC IDEA

- Logarithms of *scale ratios* appear in perturbative calculations
 - Logarithms become large when scales become hierarchical

$$\log \frac{m}{E_J}, \quad \log R = \log \frac{\text{scale 1}}{\text{scale 2}}?$$

- In effective field theories, logarithms are resummed using renormalization group evolution between characteristic scales
 - To resum *all* the logarithms we need to identify *all* the relevant scales in EFT

Soft-Collinear Effective Theory (SCET)

- Effective field theory techniques are most useful when there is clear scale separation
- SCET separates physical degrees of freedom in QCD by a systematic expansion in power counting
 - Match SCET with QCD at the hard scale by integrating out the **hard** modes
 - Integrating out the off-shell modes gives **collinear Wilson lines** which describe the collinear radiation
 - The soft sector is described by **soft Wilson lines** along the jet directions
- At leading power, soft-collinear decoupling holds in the Lagrangian and it leads to the factorization of cross sections

Power counting in SCET

- The scaling of modes in lightcone coordinates:

$$p_h : E_J(1, 1, 1), p_c : E_J(1, \lambda^2, \lambda) \text{ and } p_s : E_s(1, R^2, R)$$

- E_J is the **hard** scale which is the energy of the jet
- λ is the **power counting** parameter ($\lambda \approx m/E_J$)
- $E_J\lambda$ is the **jet** scale which is significantly lower than E_J
- Jet mass is sensitive to c-soft modes: ultrasoft modes constrained inside jets

$$E_s = E_J \frac{\lambda^2}{R^2} = \frac{m^2}{E_J R^2}$$

- QCD = $\mathcal{O}(\lambda^0) + \mathcal{O}(\lambda^1) + \dots$ in SCET

- Leading-power contribution in SCET is a very good approximation

Factorization theorem

- The cross section differential in photon p_T , y , and jet mass m can be first factorized as a convolution with parton distribution functions

$$\frac{d^2\sigma}{dp_T dy dm^2} = \frac{2}{p_T} \sum_{ab} \int dv dw \, x_1 f_a(x_1, \mu) \, x_2 f_b(x_2, \mu) \frac{d^2\hat{\sigma}}{dw dv dm^2},$$

where

$$x_1 = \frac{1}{w} \frac{p_T}{E_{CM} v} e^y, \quad x_2 = \frac{p_T}{E_{CM}(1-v)} e^{-y}$$

- The partonic cross section can be further factorized in SCET as a convolution of the hard, jet and soft function

$$\begin{aligned} \frac{d^2\hat{\sigma}}{dw dv dm^2} &= w \, \hat{\sigma}(v) \, H(p_T, v, \mu) \int dk_{in} dk_{out} dp^2 J(p^2, \mu) S(k_{in}, k_{out}, \mu) \\ &\quad \times \delta(m^2 - p^2 - 2E_J k_{in}) \delta(m_X^2 - m^2 - 2E_J k_{out}) \end{aligned}$$

where $m_X^2 = (p_J + k_{in} + k_{out})^2$ is the partonic mass of the event

Scale hierarchy and renormalization group evolution

- Each factorized piece \mathcal{O} captures physics at certain characteristic scale $\mu_{\mathcal{O}}$
 - Caveat: the soft sector is multi-scaled and needs to be *refactorized*
- The renormalization group evolution between characteristic scales resums the logs of the scale ratios

$$\mu \frac{d\mathcal{O}}{d\mu} = \gamma_{\mathcal{O}} \mathcal{O}$$

- The anomalous dimension $\gamma_{\mathcal{O}}$ can be calculated order-by-order in perturbation theory

Resummed cross section

- For the $q\bar{q} \rightarrow g\gamma$ channel,

$$\begin{aligned}
\frac{d^2 \hat{\sigma}_{q\bar{q}}}{d\omega d\nu dm^2} &= w \hat{\sigma}_{q\bar{q}}(\nu) \exp[(4C_F + 2C_A)S(\mu_h, \mu) - 4C_A S(\mu_j, \mu) + 2C_A S(\mu_{in}, \mu)] \\
&\times \exp[-4C_F S(\mu_{out}, \mu) - 2A_H(\mu_h, \mu) + 2A_{J_g}(\mu_j, \mu)] \\
&\times \exp[+2A_{S_{q\bar{q}}}(\mu_{in}, \mu) + 2A_{S_{nq\bar{q}}}(\mu_{out}, \mu)] \\
&\times \frac{\alpha_s(\mu_h)}{\alpha_s(\mu)} \left(\frac{1}{r^2} - \beta^2\right)^{-C_F A_\Gamma(\mu_{in}, \mu_{out})} \left(\frac{1}{r^2} - \frac{1}{\beta^2}\right)^{-C_F A_\Gamma(\mu_{in}, \mu_{out})} \\
&\times \left[\frac{\beta^2}{(1 + \beta^2)^2}\right]^{-C_A A_\Gamma(\mu_{in}, \mu_{out})} \left(\frac{1 + r^2}{r^2}\right)^{(2C_F - C_A) A_\Gamma(\mu_{in}, \mu_{out})} \\
&\times (\nu\bar{\nu})^{2C_F A_\Gamma(\mu_h, \mu)} \left(\frac{p_T^2}{\mu_h^2}\right)^{-(2C_F + C_A) A_\Gamma(\mu_h, \mu)} \left(\frac{\mu_j^2}{p_T \mu_{in}}\right)^{-2C_A A_\Gamma(\mu_{in}, \mu)} \\
&\times H_{q\bar{q}}(p_T, \nu, \mu_h) \tilde{J}_g(\partial_{\eta_{q\bar{q}}}, \mu_j) \tilde{S}_{q\bar{q}}(\ln \frac{\mu_j^2}{p_T \mu_{in}} + \partial_{\eta_{q\bar{q}}}, \mu_{in}) \tilde{S}_{nq\bar{q}}(\partial_{\eta_2^s}, \mu_{out}) \\
&\times \frac{1}{m_R^2(m_X^2 - m^2)} \left(\frac{m^2}{\mu_j^2}\right)^{\eta_{q\bar{q}}} \left(\frac{m_X^2 - m^2}{p_T \mu_{out}}\right)^{\eta_2^s} \frac{e^{-\gamma_E \eta_{q\bar{q}}}}{\Gamma[\eta_{q\bar{q}}]} \frac{e^{-\gamma_E \eta_2^s}}{\Gamma[\eta_2^s]}
\end{aligned}$$

where

$$\eta_{q\bar{q}} = 2C_A A_\Gamma(\mu_j, \mu_{s_{in}}), \quad \eta_2^s = 4C_F A_\Gamma(\mu_{s_{out}}, \mu)$$

Results

- The most precise analytic calculation of jet mass distributions to date
- Agree nicely with PYTHIA partonic calculation within theoretical uncertainty
 - Comparison with data will be performed
- Hadronization effect plays a role as shown in PYTHIA simulations
 - Analytic study of nonperturbative soft matrix element will be included
- Jet radius dependence correctly captured

Multiple scattering in a medium

- Coherent multiple scattering and induced bremsstrahlung are the qualitatively new ingredients in the medium parton shower
- Interplay between several characteristic scales:
 - Debye screening scale μ
 - Parton mean free path λ
 - Radiation formation time τ
- From thermal field theory and lattice QCD calculations, an ensemble of quasi particles with debye screened potential and thermal masses is a reasonable parameterization of the medium properties

$$\frac{1}{\sigma_{el}} \frac{d\sigma_{el}}{d^2 q_{\perp}} = \frac{\mu^2}{\pi(q_{\perp}^2 + \mu^2)^2}$$

SCET with Glauber gluons (SCET_G)

- Glauber gluon is the relevant mode for medium interactions
- SCET_G was constructed from SCET bottom up (Idilbi et al, Vitev et al)
 - Glauber momentum scales as $p_G : Q(\lambda^2, \lambda^2, \lambda)$
 - Glauber gluons are off-shell modes providing momentum transfer transverse to the jet direction
 - Glauber gluons are treated as background fields generated from the color charges in the QGP
 - Glauber gluons interact with both the collinear and the soft modes
- Given a medium model, we can use SCET_G to consistently couple the medium to jets

Medium-induced splitting

- The hierarchy between τ and λ determines the degree of coherence between multiple scatterings

$$\tau = \frac{x \omega}{(q_{\perp} - k_{\perp})^2} \quad \text{v.s.} \quad \lambda$$

- Medium-induced splitting functions were calculated using SCET_G (Ovanesyan et al)

$$\frac{dN_{q \rightarrow qg}^{med}}{dx d^2 k_{\perp}} = \frac{C_F \alpha_s}{\pi^2} \frac{1}{x} \int_0^L \frac{d\Delta z}{\lambda} \int d^2 q_{\perp} \frac{1}{\sigma_{el}} \frac{d\sigma_{el}}{d^2 q_{\perp}} \frac{2k_{\perp} \cdot q_{\perp}}{k_{\perp}^2 (q_{\perp} - k_{\perp})^2} \left[1 - \cos \left(\frac{(q_{\perp} - k_{\perp})^2 \Delta z}{x\omega} \right) \right]$$

- $\frac{dN^{med}}{dx d^2 k_{\perp}} \rightarrow \text{finite as } k_{\perp} \rightarrow 0$: the Landau-Pomeranchuk-Migdal effect

NLL jet mass function

- At NLL accuracy, we can define a jet-by-jet jet mass function $J_M(m^2, \mu)$ which captures all the soft-collinear radiation

$$J_M(m^2, \mu) = \int dp^2 dk J(p^2, \mu) S_{in}(k, \mu) \delta(m^2 - p^2 - 2E_J k)$$

- Medium-induced splitting functions can be used to calculate the modification of $J_M(m^2, \mu)$ as a power correction

$$J_M^i(m^2, \mu) = \sum_{j,k} \int_{PS} dx dk_{\perp} \mathcal{P}_{i \rightarrow jk}(x, k_{\perp}) \delta(m^2 - M^2(x, k_{\perp}))$$

- The full jet mass distribution can be calculated by weighting the jet mass functions with jet cross sections

$$\frac{d\sigma}{dm^2} = \sum_{i=q,g} \int_{PS} dp_T dy \frac{d\sigma^i}{dp_T dy} \frac{J_M^i(m^2, \mu)}{J_{un}^i(\mu)}$$

- Results: stay tuned before Hard Probes 2016

Conclusions and outlooks

- Jet mass in proton and heavy ion collisions can be calculated within the same framework
 - Promising agreement with PYTHIA in pp and phenomenological applications
- Expect the modification of jet mass to be a combination of cross section suppression and jet-by-jet broadening
- Work in progress and future work
 - Examine the Glauber-soft interactions
 - Calculate jet mass function modifications
 - Construct SCET at finite temperature
 - Study hadronization in the medium

Conclusions and outlooks

- The physics of heavy ion collisions is a multi-disciplinary subject
- The study of jet quenching is a unique opportunity to probe non-perturbative QCD physics with perturbative objects
- Effective field theory techniques can make important contributions
